

Designing tests for ML libraries – lessons from the wild

Benjamin Bossan & Sayak Paul

Hugging Face 🤗

PyData Amsterdam, September 2025 🇳🇱

Introduction

\$who

Benjamin is part of the `PEFT` team at Hugging Face. He is working on enabling the training of large models on modest hardware.

Sayak is the part of the `Diffusers` team at Hugging Face. He's involved in a number of applied research initiatives in the area of image and video generation.

Outline

- Revisiting the existing topic of tests 🙋
- A bit about ML libraries and their kinds
- Approaching tests for the OSS libraries at 🙌
- Practical concerns and how we address them
 - With concrete examples and links to the code
- Miscellaneous topics related to testing

Revisiting tests

ML libraries differ from regular Python libraries, which impacts testing

- Data dependency
- Compute and memory bottlenecks
- Non-deterministic outcomes
- Hardware and accelerator dependency

The big 🐘 – ML libraries

- Platform-level (`torch`, `jax`)
- Modeling (`transformers`, `diffusers`)
- Utility (`peft`, `trl`, `axolotl`)
- Data and IO (`torchvision`, `webdataset`, `datasets`)

We discuss `Diffusers` and `PEFT` in this talk 🙌

Diffusers and PEFT

-  [Diffusers](#) provides a unified interface to work with state-of-the-art open models for diffusion-based {image, video, audio}-generation.
-  [PEFT](#) implements numerous methods for parameter-efficient fine-tuning of PyTorch models on modest hardware.
- Together, 10M monthly PyPI downloads, 50k GitHub stars

The 🤗 approach to tests

Library functionality drives test design

- Tests differ from library to library, depending on the type
- For a modeling library like `Diffusers`, it's generally a collection of implementations of SoTA models:

Library functionality drives test design

- Tests differ from library to library, depending on the type
- For a modeling library like `Diffusers`, it's generally a collection of implementations of SoTA models:
 - Quantization support
 - Gradient checkpointing support
 - Fast weight loading
 - Parallelism support
 - Parameter offloading
 - and more ...

Library functionality drives test design

- Tests differ from library to library, depending on the type
- For a utility library like `PEFT`, it's generally a collection of different methods that are tested for functionality:

Library functionality drives test design

- Tests differ from library to library, depending on the type
- For a utility library like PEFT, it's generally a collection of different methods that are tested for functionality:
 - Training with these methods works
 - Methods work with different model types (decoder only, encoder-decoder, ...)
 - Methods support full range of PEFT API (saving/loading, merging, ...)
 - Quantization
 - ...

Library functionality drives test design

Common tests shared by the model implementations shipped in the library

```
1 def test_enable_disable_gradient_checkpointing(...):
2     ...
3 def test_effective_gradient_checkpointing(...):
4     ...
5 def test_gradient_checkpointing_is_applied(...):
6     ...
7 def test_deprecated_kwargs(...):
8     ...
9 def test_save_load_lora_adapter(...):
10    ...
11 def test_lora_wrong_adapter_name_raises_error(...):
12    ...
13 def test_lora_adapter_metadata_is_loaded_correctly(...):
14    ...
15 def test_lora_adapter_wrong_metadata_raises_error(...):
16    ...
17 def test_cpu_offload(...):
18    ...
```

Dealing with slow tests

- Testing pre-trained models is slow
 - Long-running test suites on PRs are a bad experience
 - Keep model configurations *minimal yet reasonable*
 - Small variants stored on HF Hub
- Tiers of frequencies in which tests are run:
 - FAST: runs on PRs, merges/pushes to main, uses small models (e.g., `peft-internal-testing/tiny-dummy-qwen2`)
 - SLOW: run on merges/pushes to main (can involve real, pre-trained models)
 - NIGHTLY: run on a nightly basis (real models, usually integration & accelerator tests)

Test matrices

- Ever growing set of models, methods, and features is supported
- Set up a base class of tests for every feature and parametrize it over models and methods
- Extension only requires adding an item to the parameter list

Test matrices

Simplified example from [PEFT tests](#):

```
1 PEFT_DECODER_MODELS_TO_TEST = [  
2     "hf-internal-testing/tiny-random-OPTForCausalLM",  
3     "hf-internal-testing/tiny-random-Gemma3ForCausalLM",  
4 ]  
5 ALL_CONFIGS = [  
6     (LoraConfig, {"task_type": "CAUSAL_LM", "r": 8}),  
7     (AdaLoraConfig, {"task_type": "CAUSAL_LM", "total_step": 1}),  
8 ]  
9  
10 class TestDecoderModels(PeftCommonTester):  
11     transformers_class = AutoModelForCausalLM  
12  
13     @pytest.mark.parametrize("model_id", PEFT_DECODER_MODELS_TO_TEST)  
14     @pytest.mark.parametrize("config_cls,config_kwargs", ALL_CONFIGS)  
15     def test_save_pretrained(self, model_id, config_cls, config_kwargs):  
16         self._test_save_pretrained(model_id, config_cls, config_kwargs)
```

Practical concerns & how we
address them

Python versions

- Test current Python versions through the test matrix
- Avoid accidentally using Python features not supported by older versions
- Some dependencies can clash with certain Python versions

Other package versions

- For critical dependencies like 🙌 Transformers, test latest source install
- Allows to catch breaking changes early
- There are specific tests for integrations (e.g., PEFT ↔ Transformers)

Operating systems

- 3 major platforms: Linux, Windows, MacOS
- PyTorch support for these platforms can differ, so testing is necessary
- MacOS-specific issues
- For `PEFT` and `Diffusers`, we also host our own runners (with GPU) but only for Linux

Concerns with large test matrices

- When testing 4 Python versions and 3 OSes, we already have 12 combinations
- Even though they can run in parallel, we have to wait for the slowest to finish
- If there are flaky tests, it's more likely that at least one run triggers it
- Leads to a 12x increase in network requests, which can result in rate limits (discussed later)

Benchmark tests

- Speed of ML models is an important concern
- Changes to the modeling code can improve/degrade speed
- We expect the baseline latency NOT to increase with changes to modeling code
- Hence the importance of benchmarking the model runtime
- This also helps improve user trust

Benchmark tests

Considerations

- Use real model checkpoints if the test infrastructure allows it
 - If not, keep the model configuration sufficiently heavy so that numbers are realistic
- If parameter offloading is used, benchmark forward passes with offloading enabled
- Only test most popular models if load is too heavy
- Thorough reporting of benchmarking results
 - Track how latency and other speed-related metrics are changing over time
 - Flag weird changes if needed

Benchmark tests

Pareto plot

Select 2 criteria to plot the Pareto frontier. This will show the best PEFT methods along this axis and the trade offs with the other axis. The PEFT methods that Pareto-dominate are shown in colors. All other methods are inferior with regard to these two metrics. Hover over a point to show details.

1st metric for Pareto plot: 2nd metric for Pareto plot:

Code coverage

Name	Stmts	Miss	Cover	Missing

src/peft/__init__.py	10	0	100%	
src/peft/auto.py	71	4	94%	61, 92, 99, 111
src/peft/config.py	133	5	96%	89, 156, 242, 267-268
src/peft/helpers.py	72	21	71%	48-58, 84-98, 124-132, 235
[...]				
src/peft/utils/warning.py	1	0	100%	

TOTAL	17430	4540	74%	

Code coverage

- High code coverage is generally desirable, coverage metrics can reveal gaps in tests
- Easily added via [pytest-cov](#)
- Due to stratification, there is no single place where all tests are run
- Monitoring test coverage is crucial for large refactors (especially refactors of the test suite itself)
- Experimental features can be added without tests at first

Regression testing

- Check that model outputs remain constant over time
- This is crucial for users, who expect backwards compatibility
- We use Hugging Face Hub to store regression artifacts

Regression testing

```
1 class TestModelRegression(RegressionTester):
2     def load_base_model(self):
3         self.fix_seed()
4         return AutoModelForCausalLM.from_pretrained(...)
5
6     def test_lora(self):
7         base_model = self.load_base_model()
8         config = LoraConfig(
9             r=8,
10            init_lora_weights=False,
11        )
12        model = get_peft_model(base_model, config)
13        self.assert_results_equal_or_store(model, <name>)
14
```

PEFT regression tests

Dealing with known failures

- ML library tests can fail in different ways:

Dealing with known failures

- ML library tests can fail in different ways:
 - Platform level (kernel bug, operator bug)
 - Python versions
 - Bugs from any required dependency

Dealing with known failures

- ML library tests can fail in different ways:
 - Platform level (kernel bug, operator bug)
 - Python versions
 - Bugs from any required dependency
- Rather than skipping, prefer using `pytest.mark.xfail` and supplement a reason and a condition
 - A better way to communicate about known failures and when they are likely to happen

Dealing with known failures

```
1 @pytest.mark.xfail(  
2     condition=torch.device(torch_device).type == "cpu"  
3     and is_torch_version(">=", "2.5"),  
4     reason="Test currently fails on CPU and PyTorch 2.5.1 but not on PyTorch 2.4.1.",  
5     strict=False,  
6 )  
7 def test_lora_fuse_nan(self):  
8     ...
```

Determinism and flakiness

- Non-determinism – outputs changing every time a model/method is run on same inputs

Determinism and flakiness

- Non-determinism – outputs changing every time a model/method is run on same inputs
- Many sources:
 - Stochastic operations inside models (instances of `torch.randn`, for example)
 - RNG seed not controlled properly (PyTorch's RNG is an advanced one)
 - Use of non-deterministic algorithms (for performance reasons)

Determinism and flakiness

- Non-determinism – outputs changing every time a model/method is run on same inputs
- Many sources:
 - Stochastic operations inside models (instances of `torch.randn`, for example)
 - RNG seed not controlled properly (PyTorch's RNG is an advanced one)
 - Use of non-deterministic algorithms (for performance reasons)
- Tests pass after a certain number of retries (can be very unreasonable sometimes) – flaky
 - Tests may pass locally in the first go
 - Tests may pass after several retries in the CI

Determinism and flakiness

- We [disable non-determinism](#) at the PyTorch level for tests where it's possible to produce non-deterministic results

```
1 def enable_full_determinism():
2     """
3     Helper function for reproducible behavior during distributed training. See
4     - https://pytorch.org/docs/stable/notes/randomness.html for pytorch
5     """
6     os.environ["CUDA_LAUNCH_BLOCKING"] = "1"
7     os.environ["CUBLAS_WORKSPACE_CONFIG"] = ":16:8"
8     torch.use_deterministic_algorithms(True)
9
10    # Enable CUDNN deterministic mode
11    torch.backends.cudnn.deterministic = True
12    torch.backends.cudnn.benchmark = False
13    torch.backends.cuda.matmul.allow_tf32 = False
```

Determinism and flakiness

For models with stochastic operations, make them accept an RNG to control that behaviour

```
1 class MyModel(torch.nn.Module):
2     def __init__(self, ...):
3         ...
4
5 -     def forward(self, ...):
6 -         ... = torch.randn(...)
7 +     def forward(self, ..., generator=None):
8 +         ... = torch.randn(..., generator=generator)
```

Determinism and flakiness

When the model needs to be invoked multiple times, re-initialize the generator each time

```
1 def test_function(model):  
2     ... = model(..., generator=torch.manual_seed(0))  
3  
4     ... = model(..., generator=torch.manual_seed(0))
```

Determinism and flakiness

To relax assertion in tests, consider using thresholds with similarity metrics (such as cosine similarity)

```
1 # Say, a tensor of shape (1, 3, 32, 32)
2 generated_output = ...
3 generated_output = generated_output.flatten()
4 generated_slices = torch.cat(
5     [generated_output[:8], generated_output[-8:]]
6 )
7
8 assert cosine_similarity_distance(generated_slices, expected_slices) < 1.0
```

Determinism and flakiness

For flaky tests mark them as such, setting maximum retries

```
1 @is_flaky(max_attempts=10, description="very flaky class")
2 class WanVACELoRATests(unittest.TestCase, PeftLoraLoaderMixinTests):
3     ...
```

Caching of models and datasets

- Often, model and dataset artifacts need to be downloaded
- Caching reduces network traffic, speeds up tests, and reduces issues like rate limits
- Session-level caching can be implemented via the testing framework (e.g. [session-scoped fixtures in pytest](#))
- Even if a HF model is cached locally, calling `AutoModel.from_pretrained` sends a request to check for updates
 - Use `local_files_only=True` or `HF_HUB_OFFLINE=1` to avoid this
- It's possible to use [GitHub cache](#) to avoid downloading all the artifacts from HF Hub

Caching of outputs

- Consider caching outputs that are reused in tests
- A good example of this is the `Diffusers-LoRA` [testing suite](#)
- Leverage `@pytest.fixture` with a class scope for this

Miscellaneous

PyTorch-specific considerations

- Use `torch.allclose` or `torch.testing.assert_close` for tensors
- Use [skip markers](#) to omit tests that require specific hardware
- Remember to set seeds before the test starts and to free memory after the test finishes
 - Can be automated with pytest fixtures: `@pytest.fixture(autouse=True)`

Checking code quality

- We enforce uniformity in terms of how code is styled and run basic QC on it
- Our preferred tool for this is `ruff` because of its speed
- Especially important as we have contributions from many outside contributors with very different backgrounds

Improving test runtime

When tests are slow:

- Identify the tests that take the most amount of time (`pytest --durations` reports are a great tool for this)
- If possible, shrink the models being used for the tests, cache outputs, etc.
- Move slow but non-essential tests to a different schedule (e.g. only run them nightly, not per PR)
- More powerful machines can run tests faster, but the first option should be preferred as it's less costly

Testing framework

- The two big testing frameworks are `unittest` (built-in) and `pytest`
- Both are very capable and used by Hugging Face
- As `pytest` is widely adopted and provides many creature comforts, we tend towards migrating to it
- We always use `pytest` as a test runner because of its many useful features:

Testing framework

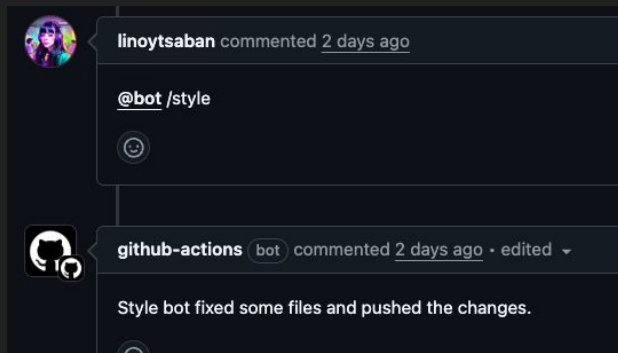

- The two big testing frameworks are `unittest` (built-in) and `pytest`
- Both are very capable and used by Hugging Face
- As `pytest` is widely adopted and provides many creature comforts, we tend towards migrating to it
- We always use `pytest` as a test runner because of its many useful features:
 - Useful options to run only subsets of tests (`pytest -m`, `pytest -k`)
 - Exit on first error (`-x`) or drop into a debugger (`--pdb`)
 - Run tests in parallel with `pytest-xdist`
 - And many more

Community contributions

- Make it easy to set up testing for all contributors (helps both maintainers and contributors)
- Make PR tests run fast without compromising library integration
- Lenient when it comes to code duplication in tests

Community contributions

- Make it easy to set up testing for all contributors (helps both maintainers and contributors)
- Make PR tests run fast without compromising library integration
- Lenient when it comes to code duplication in tests
- Use automated bots when needed

Conclusion

- Tests for ML libraries can differ in many aspects from regular libraries
- Testing should be a first class concern of your project
- Tests should be wide to cover all use cases, a select amount of tests should be deep to verify the details
- When facing constraints, prioritize and stratify the tests
- Use the breadth of your tools to make life easier
